Submodule 35.07: The Git Clone Command

1. What is Cloning?

Cloning is the process of creating an exact local copy of a remote Git repository on your physical computer. When you clone a repository, Git does not simply download the raw files; it downloads:

- All source code and assets.
- The complete commit history and log.
- All branches and tags.
- The hidden `.git/` directory containing all version control metadata.
- Automatically configures a remote reference named `origin` pointing back to the cloud repository URL.

---

2. Command Syntax & Usage

```
git clone <repository_url>
```

Step-by-Step Cloning Workflow:

1. Navigate to the target repository on GitHub (e.g., `https://github.com/delta-student/delta-demo`).
2. Click the green `<> Code` button.
3. Copy the repository URL under the **HTTPS** tab (e.g., `https://github.com/delta-student/delta-demo.git`).
4. Open your terminal and navigate to the directory where you want the project folder created.
5. Execute the clone command:

   ```
   git clone https://github.com/delta-student/delta-demo.git
   ```

6. Enter the newly cloned directory:

   ```
   cd delta-demo
   ```

---

3. What Clone Does Behind the Scenes

Verifying the Cloned Repository:

```
# Check contents (including hidden .git folder)
ls -la

# Verify configured remote URL
git remote -v
```

Expected Output of `git remote -v`:

```
origin  https://github.com/delta-student/delta-demo.git (fetch)
origin  https://github.com/delta-student/delta-demo.git (push)
```
